ON THE COHEN-MACAULAY GRAPHS AND GIRTH

DÔ TRONG HOANG, NGUYÊN CÔNG MINH, AND TRÂN NAM TRUNG

Abstract. In this paper we investigate the Cohen-Macaulay property of graphs versus girth. In particular, we classify Cohen-Macaulay graphs of girth at least five and planar Gorenstein graphs of girth four.

Introduction

In this paper, all graphs will be assumed to be simple (i.e., a finite, undirected, loopless and without multiple edges). For a graph G we denote $V(G)$ and $E(G)$ to be the vertex set and the edge set of G, respectively.

Let $R = k[x_1, \dots, x_n]$ be a polynomial ring of variables $x_1, \dots, x_n$ over the field k. Let G be a graph with $V(G) \subseteq \{x_1, \dots, x_n\}$. We associate to the graph G a quadratic squarefree monomial ideal

$$I(G) = (x_ix_j \mid x_ix_j \in E(G)) \subseteq R,$$

which is called the edge ideal of G. G is called a Cohen-Macaulay graph (resp. Gorenstein) if the edge ideal $I(G)$ is Cohen-Macaulay (resp. Gorenstein). Two vertices u, v of G are adjacent if uv is an edge of G. An independent set in G is a set of vertices no two of which are adjacent to each other. An independent set of maximum size will be referred to as a maximum independent set of G, and the independence number of G, denoted by $\alpha(G)$, is the cardinality of a maximum independent set in G. An independent set S in G is maximal (with respect to set inclusion) if the addition to S of any other vertex in the graph destroys the independence. A graph is called well-covered if every maximal independent set has the same size (see [P1], [P2]).

If G is Cohen-Macaulay, then G is well-covered by [Vi, Proposition 6.1.21]. Characterize combinatorial Cohen-Macaulay graphs is impossible because the Cohen-Macaulay property of graphs is dependent on the characteristic of the base field (see [Vi, Exercise 5.3.31]). Then, the work on Cohen-Macaulay graphs now has focused on certain class of graphs as: chordal graphs, bipartite graphs and so on (see [HH1], [HHZ], [MKY],[W1],[W2]). In here, we will give a combinatorial classification all Cohen-Macaulay graphs in some new classes.

The girth of a graph G, denoted by girth(G), is the length of any shortest cycle in G or in the case G is a forest we consider the girth to be infinite. If $X \subseteq V(G)$,

then $G[X]$ is the subgraph of G spanned by X. By $G \setminus W$, we mean the induced subgraph $G[V \setminus W]$ for some $W \subseteq V(G)$. The neighborhood of a vertex v of G is the set $N_G(v) = \{w \mid w \in V(G) \text{ and } vw \in E(G)\}$, and let $N_G[v] = N_G(v) \cup \{v\}$; if there is no ambiguity on G, we use $N(v)$ and $N[v]$, respectively.

A vertex v of G is said to be simplicial if the induced subgraph of G on the set $N[v]$ is a complete graph and we say this complete graph to be a simplex of G. A 5-cycle C_5 of a graph G is called basic, if C_5 does not contain two adjacent vertices of degree three or more in G (see [FHN1]). We call a 4-cycle C_4 basic if it contains two adjacent vertices of degree two, and the remaining two vertices belong to a simplex or a basic 5-cycle of G. A graph G is in the class $\mathcal{SQC}$, if $V(G)$ can be partitioned into three disjoint subsets S, Q, and C: The subset S contains all vertices of the simplexes of G, and the simplexes of G are vertex disjoint; the subset C consists of the vertices of the basic 5-cycles and the basic 5-cycles form a partition of C; the remaining set Q contains all vertices of degree two of the basic 4-cycles. The class $\mathcal{SQC}$ is a subclass of the class of well-covered graphs (see [RV]). The first main result of the paper, Theorem 2.3, proves that all graphs in the such class are vertex decomposable. Together this result and results of Finbow, Hartnell and Nowakowski about characterizing well-covered graphs with girths at least 5 ([FHN1]) and well-covered graphs in which triangles are allowed, but which have no 4-cycles nor 5-cycles ([FHN2]), we also can combinatorially characterize all Cohen-Macaulay graphs of girth at least five and Cohen-Macaulay graphs of girth three having no 4- nor 5-cycles (see Theorem 3.1 and 3.3).

A well-covered graph is called 1-well-covered if and only if the deletion of any point from the graph leaves a graph that is also well-covered. A well-covered graph is in the class W_2 if and only if any two disjoint independent sets in the graph can be extended to disjoint maximum independent sets. Staples [Sp] showed that a well-covered graph is 1-well-covered if and only if it is in the class W_2. Pinter [Pi1] characterized the planar graphs of girth 4 in the such class. Using this result, we also can classify all Gorenstein planar graphs in this class (Theorem 3.10).

The paper consists of three sections. In section 1, we set up some basic notations, terminologies for the simplicial complex and the graph. Section 2 is devoted to prove that all graphs in the class $\mathcal{SQC}$ are vertex decomposable. In the last section, we will prove the main results Theorem 3.1, 3.3 and 3.10.

1. PRELIMINARIES

For the detailed information about combinatorial and algebraic background we get from [S], [HH] and [Vi]. We also will use some notation on graphs according to [D]. Let Δ be a simplicial complex on $\{x_1, \ldots, x_n\}$. The Stanley-Reisner ideal of the simplicial complex Δ is a squarefree monomial ideal

$$I_\Delta = (x_{j_1} \cdots x_{j_i} \mid j_1 < \cdots < j_i \text{ and } \{j_1, \ldots, j_i\} \notin \Delta) \subseteq R.$$

The k-algebra $k[\Delta] = R/I_\Delta$ is called the Stanley-Reisner ring of Δ. We say that Δ is Cohen-Macaulay (resp. Gorenstein) (over k) if $k[\Delta]$ is Cohen-Macaulay (resp.

Gorenstein). The dimension of a face $F \in \Delta$ is $\dim F = |F| - 1$, where $|F|$ stands for the cardinality of F, and the dimension of Δ is $\dim \Delta = \max\{\dim F \mid F \in \Delta\}$.

A simplicial complex Δ (not necessarily pure) is recursively defined to be vertex decomposable if it is either a simplex or else has some vertex v so that:

(1) both $\Delta \setminus v$ and $\mathrm{lk}_\Delta v$ are vertex decomposable, and
(2) no face of $\mathrm{lk}_\Delta(v)$ is a facet of $\Delta \setminus v$.

Vertex decompositions were introduced in the pure case by Provan and Billera [PB] and extended to non-pure complexes by Björner and Wachs in [BW, Section 11].

Now, let G be a simple graph and $\Delta(G)$ the set of all independent sets in G. Then $\Delta(G)$ is a simplicial complex and is the so-called the independence complex of G. Note that $I(G) = I_{\Delta(G)}$ and $\dim(\Delta(G)) = \alpha(G) - 1$. A graph is called a vertex decomposable graph if so is its independence complex. In order to study the vertex decomposability of a graph, it suffices to study the vertex decomposability of every its component.

Lemma 1.1 (W1, Lemma 20)**.** *G is vertex decomposable if and only if all its connected components are vertex decomposable.*

For any vertex $v \in V(G)$, let $G_v = G \setminus N_G[v]$. We will use the following to check the vertex decomposable property of a graph.

Lemma 1.2 (W1, Lemma 4)**.** *A graph G is vertex decomposable if G is a totally disconnected graph (with no edges) or if it has some vertex v so that:*

(1) $G \setminus v$ and G_v are both vertex decomposable, and
(2) no independent set in G_v is a maximal independent set in $G \setminus v$.

2. A CLASS OF VERTEX DECOMPOSABLE GRAPHS

Recall that a 5-cycle C_5 of a graph G is called basic, if C_5 does not contain two adjacent vertices of degree three or more in G; a 4-cycle C_4 is called basic, if it contains two adjacent vertices of degree two, and the remaining two vertices belong to a simplex or a basic 5-cycle of G. A graph G is in the class $\mathcal{SQC}$ if there are simplicial vertices $x_1, \ldots, x_m$; basic 5-cycles $C^1, \ldots, C^s$; and basic 4-cycles $Q^1, \ldots, Q^t$ such that

$$V(G) = \bigcup_{j=1}^{m} N[x_j] \cup \bigcup_{j=1}^{s} V(C^j) \cup \bigcup_{j=1}^{t} B(Q^j)$$

and this forms a partition of $V(G)$, where $B(Q^j)$ is the set of two vertices of degree 2 of the basic 4-cycle Q^j. Such the graph G is well-covered [RV, Theorem 3.1]. Moreover, since the proof of this result, we also have a formula to compute the cardinality of a maximum independent set of such the graph

$$\alpha(G) = m + 2s + t.$$

The main result of this section says that all the graphs G in the class $\mathcal{SQC}$ are vertex decomposable. The proof is divided some steps. First, one can see that this assertion holds for well-covered simplicial graphs. A graph G is said to be simplicial if every vertex of G belongs to a simplex of G. Using a characterization due to Prisner, Topp and Vestergaard in [PTV, Lemma 2], one can see that all well-covered simplicial graph belong to the class $\mathcal{SQC}$.

Lemma 2.1 (W2, Corollary 5.5)**.** *If G is a (well-covered) simplicial graph, then G is vertex decomposable.*

Next, we will show that a graph is vertex decomposable if it belongs to the class $\mathcal{SC}$. A simple graph G is called in the class $\mathcal{SC}$ if $V(G)$ can be partitioned into two disjoint subsets S and C: the subset S contains all vertices of the simplexes of G, and the simplexes of G are vertex disjoint; the subset C consists of the vertices of the basic 5-cycles and the basic 5-cycles form a partition of C. Obviously, the class $\mathcal{SC}$ is a subclass of the class $\mathcal{SQC}$.

Lemma 2.2. *If G is a graph in the class $\mathcal{SC}$, then G is vertex decomposable.*

Proof. We prove by induction on $|V(G)|$. If $|V(G)| < 5$, then G is simplicial. Therefore, our assertion is followed from Lemma 2.1.

Assume that $|V(G)| \geq 5$. If G is disconnected, let $G_1, \ldots, G_m$ be components of G. Note that each G_i is also in the class $\mathcal{SC}$. Since $|V(G_i)| < |V(G)|$, by the induction hypothesis, G_i is vertex decomposable. Therefore, by [W1, Lemma 20], G is also vertex decomposable.

If G is connected. Let $C^1, \ldots, C^s$ be basic 5-cycles and $x_1, \ldots, x_t$ simplicial vertices of G such that

$$V(C^1), \ldots, V(C^s), N[x_1], \ldots, N[x_t]$$

form a partition of $V(G)$. If $s = 0$, then the assertion is followed from Lemma 2.1. So, we may assume that $s \geq 1$. Write $C^1 = \{xy, yz, zu, uv, vx\}$ with $\deg_G(x) \geqslant 3$.

We first claim that $G \setminus x$ is vertex decomposable. Let $H = G \setminus x$. Since C^1 is a basic 5-cycle of G, we imply that $\deg_H(y) = \deg_H(v) = 1$. Therefore, $C^2, \ldots, C^s$ are also basic 5-cycles of H and $x_1, \ldots, x_t, y, v$ are simplicial vertices of H. Clearly,

$$V(H) = V(C^2) \cup \cdots \cup V(C^s) \cup N_H[x_1] \cup \cdots \cup N_H[x_t] \cup N_H[y] \cup N_H[v]$$

and this is a partition of $V(H)$. In particular, H belongs to $\mathcal{SC}$. Futhermore, $|V(H)| = |V(G)| - 1$, by induction, H is vertex decomposable, as claimed.

We next claim that G_x is vertex decomposable. Let $L = G_x$. Since C^1 is a basic 5-cycle, so either z or u has degree 2. Assume that $\deg_G(z) = 2$, so that z is a simplicial vertex of L. Without loss of generality, we may assume that $C^2, \ldots, C^m$ are all basic 5-cycles which have vertices connect to x. Observe that $C^{m+1}, \ldots, C^s$ are basic 5-cycles of L and $x_1, \ldots, x_t$ are simplicial vertices of L. For each $i = 2, \ldots, m$, let c_i be a vertex of C^i that is incident with x in G. Let u_i and v_i be two adjacent vertices of c_i in the cycle C^i. It implies that u_i and v_i are two simplicial vertices of L (because their degree in G equal 2) and

$$V(C^{m+1}), \ldots, V(C^s), N_L[z], N_L[u_2], N_L[v_2], \ldots, N_L[u_m], N_L[v_m], N_L[x_1], \ldots, N_L[x_t]$$

form a partition of $V(L)$. In particular, L is in the class $\mathcal{SC}$. Clearly, $|V(L)| < |V(G)|$, so by induction, L is also vertex decomposable.

Since $\alpha(H) = 2(s-1) + (t+2) = 2s+t$ and $\alpha(L) = 2(s-m) + 1 + 2(m-1) + t = 2s+t-1 = \alpha(H) - 1$, by Lemma 1.2, we have G is Cohen-Macaulay as required. $\square$

We now in position to prove the main result of this section.

Theorem 2.3. *If G is a graph in the class $\mathcal{SQC}$, then G is vertex decomposable. In particular, the such graph is Cohen-Macaulay.*

Proof. We prove by induction on $|V(G)|$. If $|V(G)| < 3$, then G is a well-covered simplicial graph. It implies that G is vertex decomposable by Lemma 2.1.

Assume that $|V(G)| \geq 3$. Let $C^1, \ldots, C^s$ be basic 5-cycles; $x_1, \ldots, x_t$ simplicial vertices; and $Q^1, \ldots, Q^m$ basic 4-cycles of G such that

$$V(G) = \bigcup_{j=1}^{t} N[x_j] \cup \bigcup_{j=1}^{s} V(C^j) \cup \bigcup_{j=1}^{m} B(Q^j)$$

and this is a partition of $V(G)$, where $B(Q^j)$ is the set of two vertices of degree 2 of the basic 4-cycle Q^j. If $m = 0$, then G is in the class $\mathcal{SC}$. Therefore, G is vertex decomposable by Lemma 2.2.

If $m \geq 1$, let $Q^1 = \{a_1b_1, b_1c, cd_1, d_1a_1\}$ be a basic 4-cycle with

$$\deg_G(a_1) = \deg_G(b_1) = 2; \deg_G(c) \geq 3; \deg_G(d_1) \geq 3.$$

Without loss of generality, we may assume that $c \in V(Q^i)$ for $i = 1, \ldots, l$ and $c \notin V(Q^i)$ for $i = l+1, \ldots, m$. Write $Q^i = \{a_ib_i, b_ic, cd_i, d_ia_i\}$ with $\deg_G(a_i) = \deg_G(b_i) = 2$ for $i = 2, \ldots, l$. Note that $a_1, b_1, \ldots, a_l, b_l$ are distinct points, but $d_1, \ldots, d_l$ may be not distinct points.

From definition, we distinguish two cases:

Case 1: c belongs to only one of the basic 5-cycles of G, say

$$C^1 = \{cu_1, u_1y_1, y_1z_1, z_1v_1, v_1c\}$$

with $\deg_G(u_1) = \deg_G(v_1) = 2$ (because the degree of c is at least 3 in G). We now claim that $H = G \setminus c$ is vertex decomposable. Since $\deg_H(b_1) = \cdots = \deg_H(b_l) = 1$, $b_1, \ldots, b_l$ are simplicial vertices of H. It is easy to check that $u_1, v_1, b_1, \ldots, b_l, x_1, \ldots, x_t$ are all simplicial vertices; $C^1, \ldots, C^{s-1}$ are basic 5-cycles; and $Q^{l+1}, \ldots, Q^m$ are basic 4-cycles of H. Moreover,

$$V(H) = N_H[u_1] \cup N_H[v_1] \cup \bigcup_{j=1}^{l} N_H[b_j] \cup \bigcup_{j=1}^{t} N_H[x_j] \cup \bigcup_{j=2}^{s} V(C^j) \cup \bigcup_{j=l+1}^{m} B(Q^j)$$

and this is a partition of $V(H)$. This follows H is in the class $\mathcal{SQC}$ and $|V(H)| = |V(G)| - 1$. Then, H is vertex decomposable by induction, as claimed. Moreover, we also obtain

$$\alpha(H) = 1 + 1 + l + t + 2(s-1) + (m-l) = t + 2s + m.$$

We next claim that $L = G_c$ is vertex decomposable. It is clear that $a_1, \ldots, a_l$ are isolated vertices of L. It means that they are simplical vertices of L. As C^1 is a basic 5-cycle, so either y_1 or z_1 has degree 2 in G. Assume $\deg_G(y_1) = 2$. Then, $\deg_L(y_1) \leq 1$ which implies that y_1 is a simplicial vertex of L.

Assume that each of $Q^{l+1}, \ldots, Q^{l+r}$ has at least one vertex being adjacent with c; and every $Q^{l+r+1}, \ldots, Q^m$ has no any vertices being adjacent with c. Write $Q^j = \{a_jb_j, b_jc_j, c_jd_j, d_ja_j\}$ with $\deg_G(a_j) = \deg_G(b_j) = 2$ and c is adjacient with c_j for all $j = l+1, \ldots, l+r$. Hence, $b_{l+1}, \ldots, b_{l+r}$ are simplicial in L.

Assume that each of $C^2, \ldots, C^p$ has at least one vertex being adjacient with c; and every $C^{p+1}, \ldots, C^s$ has no any vertices being adjacient with c. For each $i = 2, \ldots, p$, let $C^i = \{u_iy_i, y_iz_i, z_iv_i, v_iw_i, w_iu_i\}$ with c and w_i are adjacent in G. So, $\deg_G(u_i) = \deg_G(v_i) = 2$. Hence, both of u_i and v_i are simplicial in L.

By definition of the class $\mathcal{SQC}$, $c \notin N_G[x_i]$ for all $i = 1, \ldots, t$. Then, x_i is also simplicial in L for all i.

In summary, L has simplicial vertices

$$y_1, a_1, \ldots, a_l, b_{l+1}, \ldots, b_{l+r}, u_2, v_2, \ldots, u_p, v_p, x_1, \ldots, x_t;$$

basic 5-cycles $C^{p+1}, \ldots, C^{s-1}$; and basic 4-cycles $Q^{l+r+1}, \ldots, Q^m$. Moreover,

$$V(L) = N_L[y_1] \cup \bigcup_{j=1}^{l} N_L[a_j] \cup \bigcup_{j=1}^{r} N_L[b_{l+j}] \cup \bigcup_{j=2}^{p} (N_L[u_j] \cup N_L[v_j]) \cup \bigcup_{j=1}^{t} N_L[x_j] \cup \bigcup_{j=p+1}^{s} V(C^j) \cup \bigcup_{j=l+r+1}^{m} B(Q_m),$$

and this is a partition of $V(L)$. It implies that L is also in the class $\mathcal{SQC}$. Hence,

$$\alpha(L) = 1 + l + r + 2(p-1) + t + 2(s-p) + (m-l-r) = t + 2s + m - 1 = \alpha(H) - 1.$$

Since $|V(L)| < |V(G)|$, also by induction, L is vertex decomposable. Using Lemma 1.2, G is vertex decomposable as required.

Case 2: c belongs to only one of the simplices $N_G[x_1], \ldots, N_G[x_t]$. In the same way as the proof of case 1, G is also vertex decomposable as required. $\square$

A vertex v of a graph G is called a cut vertex of G if $G \setminus v$ has more components than G. A connected graph with no cut vertex is called a block. A block of a graph G is a subgraph of G which is itself a block and which is maximal with respect to that property. A graph G is called a block-cactus graph if every block is complete or a cycle. As a consequence of our theorem, one has the following characterization of Cohen-Macaulay block-cactus graphs which is independent of the field.

Corollary 2.4. *Let G be a block-cactus graph. Then the following statements are equivalent:*

(1) *G is well covered and vertex decomposable.*

(2) *G is Cohen-Macaulay.*

(3) *G is in the class $\mathcal{SQC}$.*

Proof. (1)$\Longrightarrow$(2) has known in more general statement (see [S]).

(2)$\Longrightarrow$(3): It suffices to prove for connected block-cactus graphs. Now, if G is Cohen-Macaulay then G is a well-covered block-cactus graph. By [RV, Theorem 3.2], G belongs to the class $\{$4-cycle, 7-cycle$\} \cup \mathcal{SQC}$. But, both of 4-cycle and 7-cycle are not Cohen-Macaulay, so G is in the class $\mathcal{SQC}$.

(3)$\Longrightarrow$(1): If G is a block-cactus graph in the class $\mathcal{SQC}$, then we are done by Theorem 2.3. $\square$

If every block of a connected bock-cactus graph G is a edge or a cycle, then G is called a cactus graph. Equivalently, G is a cactus graph if and only if it is connected and two cycles have at most one vertex in common. A 3-cycle is called basic if it contains at least one vertex of degree two. Note that a pendant edge in a graph is any edge incident with a vertex of degree 1. Now, Corollary 2.4 can restate more explicitly in a combinatorial way for Cohen-Macaulay cactus graphs as follows (see [MKY]).

Corollary 2.5. *Let G be a cactus graph. Then the following statements are equivalent:*

1. *G is well covered and vertex decomposable.*
2. *G is Cohen-Macaulay.*
3. *G satisfies two following conditions:*
    - (a) *every vertex of degree 2 is incident with only one pendant edge or one basic 3-cycle or one basic 4-cycle or one basic 5-cycle;*
    - (b) *every vertex of degree at least 3 is incident with only one pendant edge or one basic 3-cycle or one basic 5-cycle.*

3. The Cohen-Macaulay Property versus girth

In this section, we characterize all Cohen-Macaulay graphs by their girths bases on the results due to Finbow, Hartnell and Nowakowski ([FHN1], [FHN2]), and Pinter[Pi1]. Recall that the girth of a graph G is the length of any shortest cycle in G. In a given graph G, let $C(G)$ denote the set of all points which belong to basic 5-cycles. Denote by $P(G)$ the set of vertices in G which are incident with pendant edges in G. G is said to belong to the class $\mathcal{PC}$ if $V(G)$ can be expressed as $P(G) \cup C(G)$, where $P(G) \cap C(G) = \emptyset$ and the pendant edges form a perfect matching of $P(G)$. If uv is a pendant edge in G with $\deg(u) = 1$, then $N[u] = \{u, v\}$. And then u is a simplicial vertex in G. This implies that the class $\mathcal{PC}$ is a subset of the class $\mathcal{SQC}$.

The first main result of this section is the characterization of Cohen-Macaulay graphs of girth at least 5.

Theorem 3.1. *Let G be a connected graph of girth at least* 5. *Then, G is Cohen-Macaulay if and only if G is either a vertex or in the class $\mathcal{PC}$.*

Proof. If G is a Cohen-Macaulay graph, then G is well covered. By [FHN1], we have either G is in the class $\mathcal{PC}$ or G is one of six exceptional graphs shown in Figure 3.

Among six exceptional graphs above, only K_1 is Cohen-Macaulay. Therefore, G is either a vertex or in the class $\mathcal{PC}$.

Conversely, if G is one vertex, then G is obviously Cohen-Macaulay. If G is in $\mathcal{PC}$, then G is in $\mathcal{SQC}$. By Theorem 2.3, G must be Cohen-Macaulay. $\square$

The following corollary is immediate.

Corollary 3.2. *Let $G \neq K_1$ be a connected graph of girth at least 6. Then, G is Cohen-Macaulay if and only if its pendant edges form a perfect matching of G.*

Next, we will characterize all Cohen-Macaulay graphs in which triangles are allowed, but have no 4- nor 5-cycles. In particular, in such the graphs no cliques of size greater than 3 can exist.

Theorem 3.3. *Let G be a graph that contains neither 4-cycles nor 5-cycles. Then, the following conditions are equivalent:*

1. *G is Cohen-Macaulay.*
2. *There are simplicial vertices $x_1, \dots, x_m$ of G such that $\deg_G(x_i) \leq 3$ for all i and $N_G[x_1], \dots, N_G[x_m]$ form a partition of $V(G)$.*
3. *G is a well-covered simplicial graph such that every simplicial vertex has degree at most 3.*

Proof. (1) $\Longrightarrow$ (2) Since G is a well-covered graph containing no 4-cycles nor 5-cycles, by [FHN2, Theorem 1.1], G is either a well-covered simplicial graph such that every simplicial vertex has degree at most 3 or one of two exceptional graphs C_7 and T_{10} shown in Figure 4. But both of C_7 and T_{10} are not Cohen-Macaulay, so G satisfies the condition as in the second statement.

(2) $\Longleftrightarrow$ (3) and (3) $\Longrightarrow$ (1) hold true by [PTV, Theorem 1] and Lemma 2.1. $\square$

Let U be a subset of the vertex set of a simplicial complex Δ. Let $\Delta \setminus U = \{F \in \Delta \mid F \cap U = \emptyset\}$ be a subcomplex of Δ. If $U = \{x\}$, then we write $\Delta \setminus x$ stand for $\Delta \setminus \{x\}$. Define for Δ on the vertex set V, $\operatorname{core}(V) = \{x \in V \mid \operatorname{st}(x) \neq V\}$ where $\operatorname{st}(x) = \{F \in \Delta \mid F \cup \{x\} \in \Delta\}$ and $\operatorname{core}(\Delta) = \{F \subseteq \operatorname{core}(V) \mid F \in \Delta\}$.

In [B], the doubly Cohen-Macaulay simplicial complexes are introduced. A simplicial complex Δ is called doubly Cohen-Macaulay (over k) if Δ is Cohen-Macaulay (over k) and for every vertex x of Δ the subcomplex $\Delta \setminus x$ is also Cohen-Macaulay (over k) of the same dimension as Δ. It is well known that if Δ is Gorenstein with $\operatorname{core}(\Delta) = \Delta$, then Δ is doubly Cohen-Macaulay (see [S, Theorem II.5.1]).

Recall that W_2 is the class of well-covered graphs G such that $G \setminus x$ are well-covered with $\alpha(G) = \alpha(G \setminus x)$ for all vertices x. Let G be a Gorenstein graph without isolated vertices, so that $\operatorname{core}(\Delta(G)) = \Delta(G)$. Hence, $\Delta(G)$ is doubly Cohen-Macaulay. It follows that for all vertices x of G, $\Delta(G) \setminus x = \Delta(G \setminus x)$ is Cohen-Macaulay with

$$\alpha(G \setminus x) = \dim \Delta(G \setminus x) + 1 = \dim \Delta(G) + 1 = \alpha(G).$$

This implies that G is in class W_2.

Pinter [Pi1] constructed a infinite family of graphs by a recursive procedure as follows:

(1) Begin with the graph G_3 shown in Figure 5;
(2) Given any graph G in the construction, let x and y be two adjacent points of degree 2 in G. Let u be the neighbor of x such that $u \neq y$. Then construct a new graph G' with precisely three more points than G as follows. Let the three new points be a, b and c. Now join a to x and b, b to c and c to u and y (see Figure 6).

Let us denote this infinite family of graphs by $\mathcal{G}$. Pinter proved the following result.

Lemma 3.4. *A connected graph G is a girth 4 planar member of class W_2 if and only if G is a member of the family $\mathcal{G}$.*

In general, two graphs G and H are isomorphic, written $G \cong H$, if there are a bijection map $\varphi : V(G) \longrightarrow V(H)$ such that $uv \in E(G) \Longleftrightarrow \varphi(u)\varphi(v) \in E(H)$ for all $u, v \in V(G)$. Although the graphs G and H are not identical, they have identical structures if they are isomorphic.

Definition 3.5. For every integer $n \geq 1$, we define two graphs G_n and H_n as follows:

(1) G_n is a graph with the vertex set $\{x_1, \ldots, x_{3n-1}\}$ and the edge set

$$\{x_1x_2, \{x_{3k-1}x_{3k}, x_{3k}x_{3k+1}, x_{3k+1}x_{3k+2}, x_{3k+2}x_{3k-2}\}_{k=1,2,\ldots,n-1}, \{x_{3l-3}x_{3l}\}_{l=2,3,\ldots,n-1}\}$$

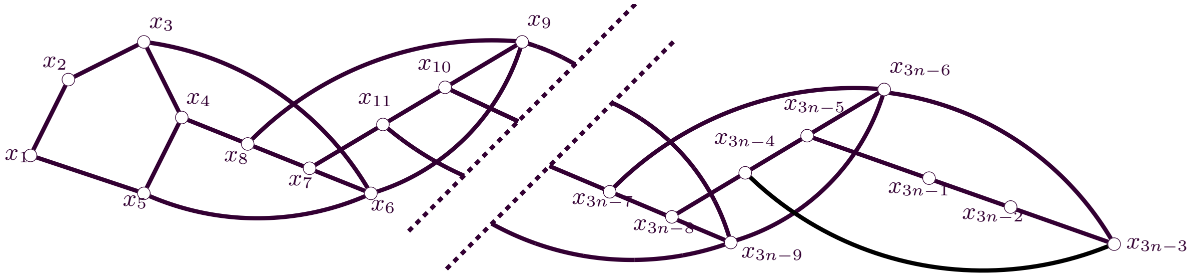

Figure 1. The graph G_n.

(2) $H_n = G_n \setminus x_{3n-1}$. It means that $V(H_n) = \{x_1, \ldots, x_{3n-2}\}$ and

$$E(H_n) = \begin{cases} \{x_1\} & \text{if } n = 1, \\ \{x_1x_2, x_2x_3, x_3x_4\} & \text{if } n = 2, \\ E(G_{n-1}) \cup \{x_{3n-2}x_{3n-3}, x_{3n-3}x_{3n-4}, x_{3n-3}x_{3n-6}\} & \text{if } n \geq 3. \end{cases}$$

Roughly speaking, the family $\mathcal{G}$ is actually $\{G_n\}_{n\geq 3}$. In fact, from the construction of $\mathcal{G}$ and Lemma 3.4, we will obtain the following.

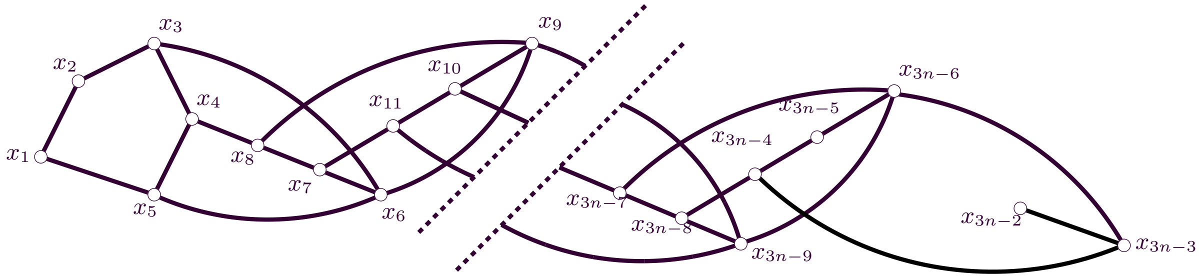

Figure 2. The graph H_n.

Lemma 3.6. *A connected planar graph G of girth 4 is a member of W_2 if and only if $G \cong G_n$ for some $n \geq 3$.*

Let G be a connected graph in the class W_2. Pinter [Pi2] proved that if $G \neq K_2$ or C_5 then $\text{girth}(G) \leq 4$. Thus, connected Gorenstein graphs with girth at least 5 is one of three graphs K_1, K_2 and C_5. So the structure of connected Gorenstein graphs is non trivial only for the ones of girth ≤ 4. In the last theorem, we will give a complete characterization of a Gorenstein connected planar graph of girth 4. Recall that the union of graphs G and H is the graph $G \cup H$ with vertex set $V(G) \cup V(H)$ and edge set $E(G) \cup E(H)$. If G and H are disjoint, we refer to their union as a disjoint union, and generally denote it by $G \sqcup H$. Firstly, we have the following observation.

Remark 3.7. Let G be a simple graph G and a point $x \in V(G)$. If both of G_x and $G \setminus x$ are well covered with $\alpha(G \setminus x) = \alpha(G_x) + 1$, then G is also well covered with $\alpha(G) = \alpha(G \setminus x)$.

Secondly, we will prove the vertex decomposability of G_n and H_n.

Lemma 3.8. *For all integers $n \geq 1$, both of G_n and H_n are well covered and vertex decomposable with $\alpha(G_n) = \alpha(H_n) = n$. In particular, G_n and H_n are Cohen-Macaulay.*

Proof. We will prove by induction on n. If $n = 1$ or $n = 2$, then our assertion holds true. If $n \geq 3$, since $H_n \setminus x_{3n-3} = G_{n-1} \sqcup \{x_{3n-2}\}$, so $H_n \setminus x_{3n-3}$ is well covered and vertex decomposable with $\alpha(H_n \setminus x_{3n-3}) = \alpha(G_{n-1}) + 1 = n$ by induction and Lemma 1.1. On the other hand, it is clear that $(H_n)_{x_{3n-3}} = G_{n-2} \sqcup \{x_{3n-5}\}$. Also by induction and Lemma 1.1, $(H_n)_{x_{3n-3}}$ is well covered and vertex decomposable with $\alpha((H_n)_{x_{3n-3}}) = \alpha(G_{n-2}) + 1 = n - 1 = \alpha(H_n \setminus x_{3n-3}) - 1$. Therefore, H_n is well covered with $\alpha(H_n) = \alpha(H_n \setminus x_{3n-3}) = n$ (by Remark 3.7) and vertex decomposable (by Lemma 1.1).

Moreover, $G_n \setminus x_{3n-1} = H_n$ is well covered and vertex decomposable with $\alpha(G_n \setminus x_{3n-1}) = n$ has done. On the other hand, one can check that $(G_n)_{x_{3n-1}} \cong G_{n-1}$. By induction, $(G_n)_{x_{3n-1}}$ is vertex decomposable and $\alpha((G_n)_{x_{3n-1}}) = n - 1$. Thus, G_n is vertex decomposable by Lemma 1.1. It is clearly that G_n is well covered with $\alpha(G_n) = n$ which is complete the proof. □

Next, one can see that $I(G_n)^2$ is Cohen-Macaulay for all integers $n \geq 1$, as conjectured by G. Rinaldo, N. Terai and K. Yoshida [RTY, Conjecture 5.7]. The case $n = 1$ is known in [MT, Theorem 3.2] and the case $n = 2$ is also mentioned in [TrT, Theorem 3.8 (iv)].

Proposition 3.9. *For all integers $n \geq 1$, $I(G_n)^2$ are Cohen-Macaulay.*

Proof. Note that G_n is a triangle-free graph, so $I(G_n)^2 = I(G_n)^{(2)}$ (see [SVV] or [RTY, Corollary 4.5]). Therefore, it suffices to prove that $I(G_n)^{(2)}$ is Cohen-Macaulay.

If $n = 1$ (resp. $n = 2$) then G_n is an edge (resp. a pentagon). Thus $I(G_n)^{(2)}$ is Cohen-Macaulay.

If $n \geq 3$, by Lemma 3.8 and [HMT, Theorem 2.3], it is enough to prove that $(G_n)_{xy}$ is Cohen-Macaulay with $\alpha((G_n)_{xy}) = n - 1$ for every edge $xy \in E(G_n)$; where $(G_n)_{xy}$ stands for $G_n \setminus (N_{G_n}(x) \cup N_{G_n}(y))$. We distinguish six following cases:

Case 1: $xy = x_1x_2$. Clearly, $(G_n)_{x_1x_2} \cong H_{n-1}$. Therefore, by Lemma 3.8, $(G_n)_{x_1x_2}$ is Cohen-Macaulay with $\alpha((G_n)_{x_1x_2}) = n$.

Case 2: $xy = x_{3k-1}x_{3k}$ for some $k = 1, \ldots, n-1$. Observe that

$$(G_n)_{x_{3k-1}x_{3k}} = \begin{cases} U_1 \sqcup \{x_5\} & \text{if } k = 1, \text{where } U_1 \cong G_{n-2} \quad (1) \\ U_2 \sqcup \{x_{3n-1}\} & \text{if } k = n-1, \text{where } U_2 \cong G_{n-2} \qquad (2) \\ U_3 \sqcup \{x_2\} \sqcup \{x_8\} & \text{if } k = 2, \text{where } U_3 \cong G_{n-3} \quad (3) \\ M \sqcup N \sqcup \{x_{3k+2}\} & \text{if } 3 \leq k < n-1, \qquad\qquad (4) \end{cases}$$

where $M = G_n[\{x_1, \ldots, x_{3k-6}, x_{3k-4}\}]$ and $N = G_n[\{x_{3k+4}, \ldots, x_{3n-1}\}]$.

In the three cases $(1) - (3)$, using Lemma 3.8 and Lemma 1.1, we have $(G_n)_{x_{3k-1}x_{3k}}$ is always Cohen-Macaulay with $\alpha((G_n)_{x_{3k-1}x_{3k}}) = n - 1$. In the last case, we define the map $\varphi : V(H_{k-1}) \longrightarrow V(M)$ as follows:

If $k = 3$ then $\varphi(x_i) = x_i$ for all $i = 1, 2, 3$ and $\varphi(x_4) = x_5$.

If $k > 3$ then $\varphi(x_i) = x_i$ for all $i = 1, \ldots, 3k-9$; $\varphi(x_{3k-8}) = x_{3k-6}, \varphi(x_{3k-7}) = x_{3k-7}, \varphi(x_{3k-6}) = x_{3k-8}$; and $\varphi(x_{3k-5}) = x_{3k-4}$.

Clearly, φ is an isomorphism of two graphs H_{k-1} and M. Therefore, M must be Cohen-Macaulay with $\alpha(M) = k-1$ by Lemma 3.8. Similarly, we have a bijection map $\psi : V(G_{n-k-1}) \longrightarrow V(N)$ is defined by $\psi(x_i) = x_{3k+3+i}$ for all $i = 1 \ldots, 3n-3k-4$. So $G_{n-k-1} \cong N$. Using again Lemma 3.8, N is Cohen-Macaulay with $\alpha(N) = n-k-1$. Thus, $(G_n)_{x_{3k-1}x_{3k}}$ is Cohen-Macaulay with

$$\alpha((G_n)_{x_{3k-1}x_{3k}}) = (k-1) + (n-k-1) + 1 = n - 1.$$

By the same argument, we will obtain the following.

Case 3: $xy = x_{3k}x_{3k+1}$ for some $k = 1, \ldots, n-1$. Then,

$$(G_n)_{x_{3k}x_{3k+1}} \cong \begin{cases} H_{n-2} \sqcup \{x_1\} & \text{if } k = 1 \\ G_{k-1} \sqcup G_{n-k-1} \sqcup \{x_{3k-2}\} & \text{if } k \geqslant 2. \end{cases}$$

Case 4: $xy = x_{3k+1}x_{3k+2}$ for some $k = 1, \ldots, n-1$. Then,

$$(G_n)_{x_{3k+1}x_{3k+2}} \cong H_{k-1} \sqcup H_{n-k-1} \sqcup \{x_{3k-1}\}.$$

Case 5: $xy = x_{3k+2}x_{3k-2}$ for some $k = 1, \dots, n-1$. Then,

$$(G_n)_{x_{3k+2}x_{3k-2}} \cong G_{k-1} \sqcup G_{n-k-1} \sqcup \{x_{3k}\}.$$

Case 6: $xy = x_{3k}x_{3k-3}$ for some $2 \leq k \leq n-1$. Then,

$$(G_n)_{x_{3k+2}x_{3k-2}} \cong G_{k-1} \sqcup G_{n-k-2} \sqcup \{x_{3k-5}\} \sqcup \{x_{3k+2}\}.$$

From six cases above, for every edge $xy \in E(G_n)$, we always obtain that $(G_n)_{xy}$ is Cohen-Macaulay with $\alpha((G_n)_{xy}) = n-1$ which completes the proof. ☐

Finally, one can see that the class of connected planar Gorenstein graphs with girth 4 is exactly $\mathcal{G}$.

Theorem 3.10. *Let G be a connected planar graph of girth 4. Then, G is Gorenstein if and only if G is in the family $\mathcal{G}$.*

Proof. If G is Gorenstein, then G is in the class W_2 (note that G has no isolated vertecies). Using Lemma 3.4, G is a member of family $\mathcal{G}$.

Conversely, if G is a member of $\mathcal{G}$, we may assume that $G = G_n$ for some $n \geq 3$. Because of Proposition 3.9, $I(G_n)^2$ is Cohen-Macaulay over any field k. Hence, by [RTY, Theorem 2.1], one has G_n must be Gorenstein as required. ☐

Acknowledgment. We would like to thank Professors N. V. Trung and L. T. Hoa for helpful comments, Professors R. Woodroofe and S. A. Seyed Fakhari for comments for vertex decomposability. Parts of this work was carried out while the second and third authors visited the University of Genoa. We acknowledge the support from EMMA in the framework of the EU Erasmus Mundus Action 2 for this visit. We would also like to thank Professor A. Conca for his hospitality.
